## Signal Descriptions

The number after the underscore ("\_") in pin names such as XXX\_1 and XXX\_2 indicates the relocated port number. For these pins, there are multiple pins that provide the same function for the same channel.

Use the extended port function register (EPFR) to select the pin.

The TAP pins may also be configurable for purposes other than access to the TAP controller.

## 6. Handling Precautions

Every semiconductor device has a characteristic, inherent rate of failure. The possibility of failure is greatly affected by the conditions in which they are used (circuit conditions, environmental conditions, etc.). This page describes precautions that must be observed to minimize the chance of failure and to obtain higher reliability from your Cypress semiconductor devices.

### 6.1 Precautions for Product Design

This section describes precautions when designing electronic equipment using semiconductor devices.

#### Absolute Maximum Ratings

Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of certain established limits, called absolute maximum ratings. Do not exceed these ratings.

#### Recommended Operating Conditions

Recommended operating conditions are normal operating ranges for the semiconductor device. All the device's electrical characteristics are warranted when operated within these ranges.

Always use semiconductor devices within the recommended operating conditions. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their sales representative beforehand.

#### Processing and Protection of Pins

These precautions must be followed when handling the pins that connect semiconductor devices to power supply and I/O functions.

##### 1. Preventing Over-Voltage and Over-Current Conditions

Exposure to voltage or current levels in excess of maximum ratings at any pin is likely to cause deterioration within the device, and in extreme cases leads to permanent damage of the device. Try to prevent such overvoltage or over-current conditions at the design stage.

##### 2. Protection of Output Pins

Shorting of output pins to supply pins or other output pins, or connection to large capacitance can cause large current flows. Such conditions, if present for extended periods of time, can damage the device; therefore, avoid this type of connection.

##### 3. Handling of Unused Input Pins

Unconnected input pins with very high impedance levels can adversely affect stability of operation. Such pins should be connected through an appropriate resistance to a power-supply pin or ground pin.

## **Latch-Up**

Semiconductor devices are constructed by the formation of p-type and n-type areas on a substrate. When subjected to abnormally high voltages, internal parasitic pnpn junctions (called thyristor structures) may be formed, causing large current levels in excess of several hundred millamps to flow continuously at the power supply pin. This condition is called latch-up.

**CAUTION:** The occurrence of latch-up not only causes loss of reliability in the semiconductor device, but can cause injury or damage from high heat, smoke or flame. To prevent this from happening, do the following:

1. Be sure that voltages applied to pins do not exceed the absolute maximum ratings. This should include attention to abnormal noise, surge levels, etc.
2. Be sure that abnormal current flows do not occur during the power-on sequence.

## **Observance of Safety Regulations and Standards**

Most countries in the world have established standards and regulations regarding safety, protection from electromagnetic interference, etc. Customers are requested to observe applicable regulations and standards in the design of products.

## **Fail-Safe Design**

As previously mentioned, all semiconductor devices have inherent rates of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions.

## **Precautions Related to Usage of Devices**

Cypress semiconductor devices are intended for use in standard applications (computers, office automation and other office equipment, industrial, communications, and measurement equipment, personal or household devices, etc.).

**CAUTION:** Customers considering the use of our products in special applications where failure or abnormal operation may directly affect human lives or cause physical injury or property damage, or where extremely high levels of reliability are demanded (such as aerospace systems, atomic energy controls, sea floor repeaters, vehicle operating controls, medical devices for life support, etc.) are requested to consult with sales representatives before such use. The company will not be responsible for damages arising from such use without prior approval.

## **6.2 Precautions for Package Mounting**

Package mounting may be either lead insertion type or surface mount type. In either case, for heat resistance during soldering, you should only mount under Cypress's recommended conditions. For detailed information about mount conditions, contact your sales representative.

### **Lead Insertion Type**

Mounting of lead insertion type packages onto printed circuit boards may be done by two methods: direct soldering on the board, or mounting by using a socket.

Direct mounting onto boards normally involves processes for inserting leads into through-holes on the board and using the flow soldering (wave soldering) method of applying liquid solder. In this case, the soldering process usually causes leads to be subjected to thermal stress in excess of the absolute ratings for storage temperature. Mounting processes should conform to Cypress recommended mounting conditions.

If socket mounting is used, differences in surface treatment of the socket contacts and IC lead surfaces can lead to contact deterioration after long periods. For this reason it is recommended that the surface treatment of socket contacts and IC leads be verified before mounting.

## **Surface Mount Type**

Surface mount packaging has longer and thinner leads than lead-insertion packaging, and therefore leads are more easily deformed or bent. The use of packages with higher pin counts and narrower pin pitch results in increased susceptibility to open connections caused by deformed pins, or shorting due to solder bridges.

You must use appropriate mounting techniques. Cypress recommends the solder reflow method, and has established a ranking of mounting conditions for each product. Users are advised to mount packages in accordance with Cypress ranking of recommended conditions.

## **Lead-Free Packaging**

**CAUTION:** When ball grid array (BGA) packages with Sn-Ag-Cu balls are mounted using Sn-Pb eutectic soldering, junction strength may be reduced under some conditions of use.

## **Storage of Semiconductor Devices**

Because plastic chip packages are formed from plastic resins, exposure to natural environmental conditions will cause absorption of moisture. During mounting, the application of heat to a package that has absorbed moisture can cause surfaces to peel, reducing moisture resistance and causing packages to crack. To prevent this, do the following:

1. Avoid exposure to rapid temperature changes, which can cause moisture to condense inside the product. Store products in locations where temperature changes are slight.
2. Use dry boxes for product storage. Products should be stored below 70% relative humidity, and at temperatures between 5°C and 30°C.
3. When Dry Packages are opened, it is recommended to have humidity between 40% and 70%.
4. When necessary, Cypress packages semiconductor devices in highly moisture-resistant aluminum laminate bags, with a silica gel desiccant. Devices should be sealed in these aluminum laminate bags for storage.
5. Avoid storing packages where they are exposed to corrosive gases or high levels of dust.

## **Baking**

Packages that have absorbed moisture may be de-moisturized by baking (heat drying). Follow the Cypress recommended conditions for baking.

Condition: 125°C/24 h

## **Static Electricity**

Because semiconductor devices are particularly susceptible to damage by static electricity, you must take the following precautions:

1. Maintain relative humidity in the working environment between 40% and 70%. Use of an apparatus for ion generation may be needed to remove electricity.
2. Electrically ground all conveyors, solder vessels, soldering irons, and peripheral equipment.
3. Eliminate static body electricity by the use of rings or bracelets connected to ground through high resistance (on the level of 1 MΩ). Wearing of conductive clothing and shoes, and the use of conductive floor mats and other measures to minimize shock loads is recommended.
4. Ground all fixtures and instruments, or protect with anti-static measures.
5. Avoid the use of Styrofoam or other highly static-prone materials for storage of completed board assemblies.

### **6.3 Precautions for Use Environment**

Reliability of semiconductor devices depends on ambient temperature and other conditions as described above.

For reliable performance, do the following:

1. Humidity

Prolonged use in high humidity can lead to leakage in devices as well as printed circuit boards. If high humidity levels are anticipated, consider anti-humidity processing.

2. Discharge of static electricity

When high-voltage charges exist close to semiconductor devices, discharges can cause abnormal operation. In such cases, use anti-static measures or processing to prevent discharges.

3. Corrosive gases, dust, or oil

Exposure to corrosive gases or contact with dust or oil may lead to chemical reactions that will adversely affect the device. If you use devices in such conditions, consider ways to prevent such exposure or to protect the devices.

4. Radiation, including cosmic radiation

Most devices are not designed for environments involving exposure to radiation or cosmic radiation. Users should provide shielding as appropriate.

5. Smoke, flame

**CAUTION:** Plastic molded devices are flammable and therefore should not be used near combustible substances. If devices begin to smoke or burn, there is danger of the release of toxic gases.

Customers considering the use of Cypress products in other special environmental conditions should consult with sales representatives.

## 7. Handling Devices

### Power-Supply Pins

In products with multiple VCC and VSS pins, respective pins at the same potential are interconnected within the device in order to prevent malfunctions such as latch-up. All of these pins should be connected externally to the power supply or ground lines, however, in order to reduce electromagnetic emission levels, to prevent abnormal operation of strobe signals caused by the rise in the ground level, and to conform to the total output current rating.

Be sure to connect the current-supply source with the power pins and GND pins of this device at low impedance. It is also advisable that a ceramic capacitor of approximately 0.1  $\mu$ F be connected as a bypass capacitor between VCC and VSS near this device.

A malfunction may occur when the power-supply voltage fluctuates rapidly even though the fluctuation is within the guaranteed operating range of the VCC power supply voltage. As a rule of voltage stabilization, suppress voltage fluctuation so that the fluctuation in VCC ripple (peak-to-peak value) at the commercial frequency (50 Hz/60 Hz) does not exceed 10% of the standard VCC value, and the transient fluctuation rate does not exceed 0.1V/ $\mu$ s at a momentary fluctuation such as switching the power supply.

### Crystal Oscillator Circuit

Noise near the X0/X1 and X0A/X1A pins may cause the device to malfunction. Design the printed circuit board so that X0/X1, X0A/X1A pins, the crystal oscillator (or ceramic oscillator), and the bypass capacitor to ground are located as close to the device as possible.

It is strongly recommended that the PC board artwork be designed such that the X0/X1 and X0A/X1A pins are surrounded by ground plane, as this is expected to produce stable operation.

Evaluate the oscillation introduced by the use of the crystal oscillator by your mount board.

### Sub Crystal Oscillator

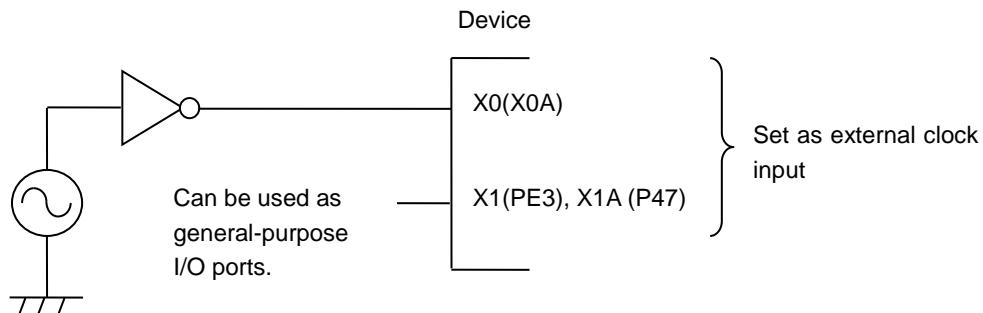

The sub-oscillator circuit for devices in this family is low gain to keep current consumption low. To stabilize the oscillation, Cypress recommends a crystal oscillator that meets the following conditions:

- Surface mount type
  - Size: More than 3.2 mm x 1.5 mm
  - Load capacitance: approximately 6 pF to 7 pF
- Lead type
  - Load capacitance: approximately 6 pF to 7 pF

## Using an External Clock

When using an external clock as an input of the main clock, set X0/X1 to the external clock input, and input the clock to X0. X1(PE3) can be used as a general-purpose I/O port. Similarly, when using an external clock as an input of the sub clock, set X0A/X1A to the external clock input and input the clock to X0A. X1A (P47) can be used as a general-purpose I/O port.

### ● Example of Using an External Clock

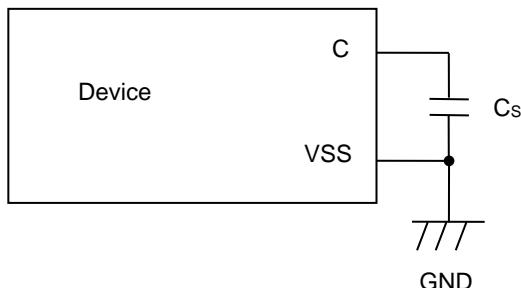

## Handling When Using Multi-Function Serial Pin as I<sup>2</sup>C Pin

If the application uses the multi-function serial pin as an I<sup>2</sup>C pin, the P-channel transistor of the digital output must be disabled. I<sup>2</sup>C pins need to conform to electrical limitations like other pins, however, and avoid connecting to live external systems with the MCU power off.

## C Pin

Devices in this series contain a regulator. Be sure to connect a smoothing capacitor (Cs) for the regulator between the C pin and the GND pin. Please use a ceramic capacitor or a capacitor of equivalent frequency characteristics as a smoothing capacitor. Some laminated ceramic capacitors have a large capacitance variation due to thermal fluctuation. Please select a capacitor that meets the specifications in the operating conditions to use by evaluating the temperature characteristics of the device. A smoothing capacitor of about 4.7  $\mu$ F would be recommended for this series.

## Mode Pins (MD0)

Connect the MD pin (MD0) directly to VCC or VSS pins. Design the printed circuit board such that the pull-up/down resistance stays low, the distance between the mode pins and VCC pins or VSS pins is as short as possible, and the connection impedance is low when the pins are pulled up/down such as for switching the pin level and rewriting the flash memory data. This is important to prevent the device from erroneously switching to test mode as a result of noise.

### Notes on Power-on

Turn power on/off in the following order or at the same time. The device operates normally after all power on.

VBAT only Power-on is possible when VBAT and VCC turns Power-on and Hibernation control is setting and then VCC turns Power-off. About Hibernation control, see Chapter 7-2: VBAT Domain(B) in FM4 Family Peripheral Manual Main Part(002-04856).

Turning on:    VBAT → VCC → USBVCC0  
                  VBAT → VCC → USBVCC1  
                  VCC → AVCC → AVRH  
Turning off:    AVRH → AVCC → VCC  
                  USBVCC1 → VCC → VBAT  
                  USBVCC0 → VCC → VBAT

### Serial Communication

There is a possibility of receiving incorrect data as a result of noise or other issues introduced by the serial communication. Take care to design the printed circuit board to minimize noise.

Consider the case of introducing error as a result of noise, perform error detection such as by applying a checksum of data at the end. If an error is detected, retransmit the data.

### Differences in Characteristics within the Product Line

The electric characteristics including power consumption, ESD, latch-up, noise, and oscillation differ among members of the product line because chip layout and memory structures are not the same; for example, different sizes, flash versus ROM, etc. If you are switching to a different product of the same series, please make sure to evaluate the electric characteristics.

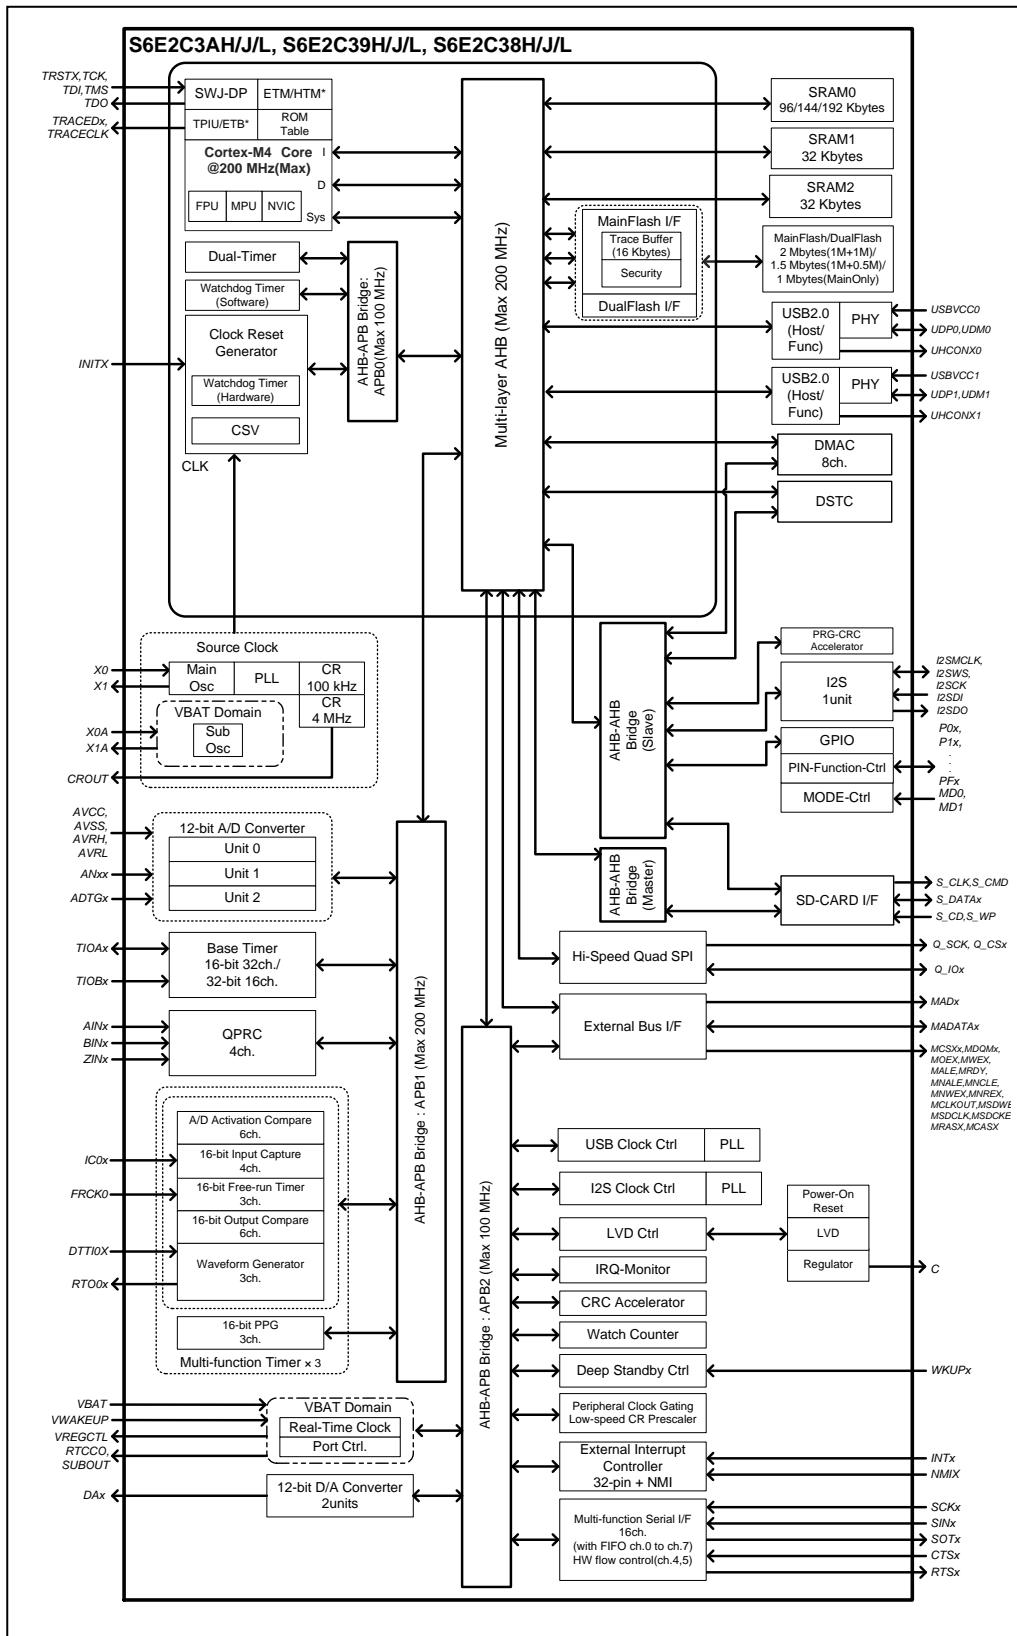

### Pull-Up Function of 5 V Tolerant I/O

Please do not input the signal more than VCC voltage at the time of Pull-Up function use of 5 V tolerant I/O.

### Pin Doubled as Debug Function

The pin doubled as TDO/TMS/TDI/TCK/TRSTX, SWO/SWDIO/SWCLK should be used as output only. Do not use as input.

## 11. Pin Status in Each CPU State

The terms used for pin status have the following meanings:

■ INITX = 0

This is the period when the INITX pin is at the L level.

■ INITX = 1

This is the period when the INITX pin is at the H level.

■ SPL = 0

This is the status that the standby pin level setting bit (SPL) in the standby mode control register (STB\_CTL) is set to 0.

■ SPL = 1

This is the status that the standby pin level setting bit (SPL) in the standby mode control register (STB\_CTL) is set to 1.

■ Input enabled

Indicates that the input function can be used.

■ Internal input fixed at 0

This is the status that the input function cannot be used. Internal input is fixed at L.

■ Hi-Z

Indicates that the pin drive transistor is disabled and the pin is put in the Hi-Z state.

■ Setting disabled

Indicates that the setting is disabled.

■ Maintain previous state

Maintains the state that was immediately prior to entering the current mode.

If a built-in peripheral function is operating, the output follows the peripheral function.

If the pin is being used as a port, that output is maintained.

■ Analog input is enabled

Indicates that the analog input is enabled.

■ Trace output

Indicates that the trace function can be used.

■ GPIO selected

In Deep standby mode, pins switch to the general-purpose I/O port.

■ Setting prohibition

Prohibition of a setting by specification limitation

$$T_A(\text{Max}) = T_J(\text{Max}) - P_d(\text{Max}) \times \theta_{JA}$$

Pd: Power dissipation (W)

θ<sub>JA</sub>: Package thermal resistance (°C/W)

$$P_d(\text{Max}) = V_{CC} \times I_{CC}(\text{Max}) + \sum (I_{OL} \times V_{OL}) + \sum ((V_{CC} - V_{OH}) \times (-I_{OH}))$$

4. Users considering application outside the listed conditions are advised to contact their representatives beforehand.

## Calculation Method of Power Dissipation (Pd)

The power dissipation is shown in the following formula.

$$P_d = V_{CC} \times I_{CC} + \sum (I_{OL} \times V_{OL}) + \sum ((V_{CC}-V_{OH}) \times (-I_{OH}))$$

$I_{OL}$ : L level output current

$I_{OH}$ : H level output current

$V_{OL}$ : L level output voltage

$V_{OH}$ : H level output voltage

$I_{CC}$  is the current drawn by the device.

It can be analyzed as follows.

$$I_{CC} = I_{CC} (\text{INT}) + \sum I_{CC} (\text{IO})$$

$I_{CC} (\text{INT})$ : Current drawn by internal logic and memory, etc. through the regulator

$\sum I_{CC} (\text{IO})$ : Sum of current (I/O switching current) drawn by the output pin

For  $I_{CC} (\text{INT})$ , it can be anticipated by (1) Current Rating in 12.3. DC Characteristics (This rating value does not include  $I_{CC} (\text{IO})$  for a value at pin fixed).

For  $I_{CC} (\text{IO})$ , it depends on system used by customers.

The calculation formula is shown below.

$$I_{CC} (\text{IO}) = (C_{INT} + C_{EXT}) \times V_{CC} \times f_{SW}$$

$C_{INT}$ : Pin internal load capacitance

$C_{EXT}$ : External load capacitance of output pin

$f_{SW}$ : Pin switching frequency

Parameter	Symbol	Conditions	Capacitance Value
Pin internal load capacitance	$C_{INT}$	4 mA type	1.93 pF
		8 mA type	3.45 pF
		12 mA type	3.42 pF

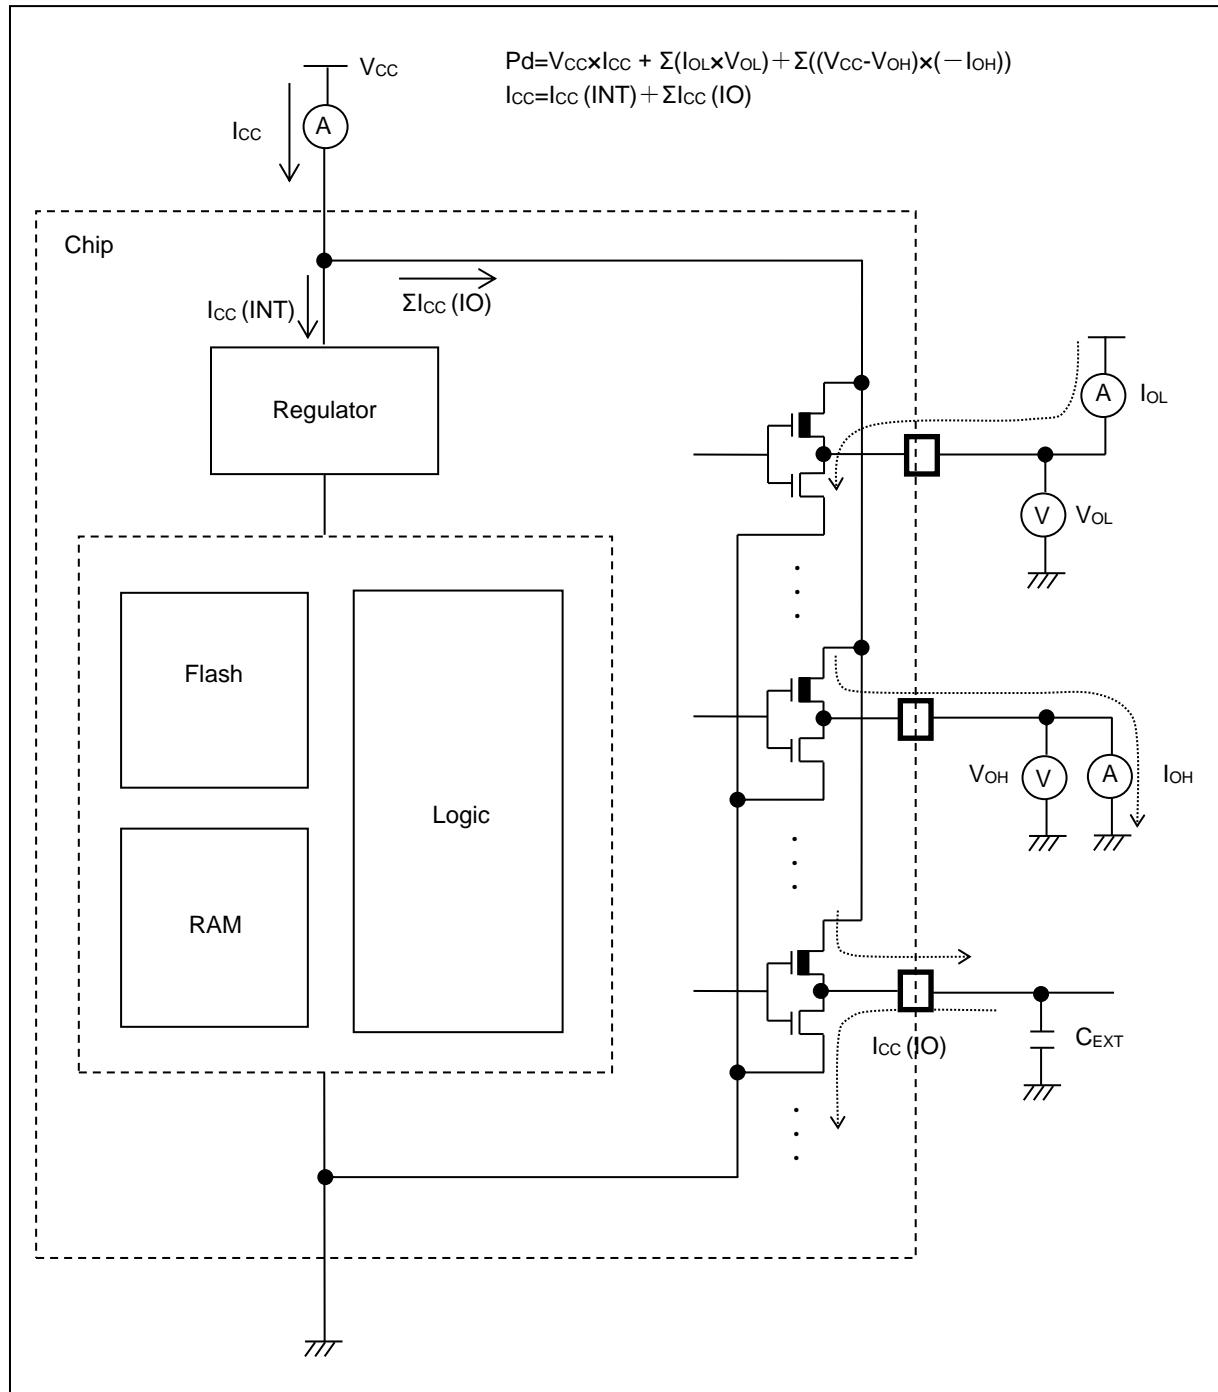

Calculate  $I_{CC}$  (Max) as follows when the power dissipation can be evaluated by yourself:

Measure current value  $I_{CC}$  (Typ) at normal temperature (+25°C).

Add maximum leakage current value  $I_{CC}$  (leak\_max) at operating on a value in (1).

$$I_{CC}(\text{Max}) = I_{CC} (\text{Typ}) + I_{CC} (\text{leak\_max})$$

Parameter	Symbol	Conditions	Current Value
Maximum leakage current at operating	$I_{CC} (\text{leak\_max})$	$T_J = +125^{\circ}\text{C}$	79.2 mA
		$T_J = +105^{\circ}\text{C}$	39.4 mA
		$T_J = +85^{\circ}\text{C}$	26.5 mA

\*3: The output drive capability of the driver is below 0.3 V at low state ( $V_{OL}$ ) (to 3.6 V and 1.5 k $\Omega$  load), and 2.8 V or above (to the VSS and 1.5 k $\Omega$  load) at high state ( $V_{OH}$ ).

\*4: The cross voltage of the external differential output signal (D+/D-) of USB I/O buffer is within 1.3 V to 2.0 V.

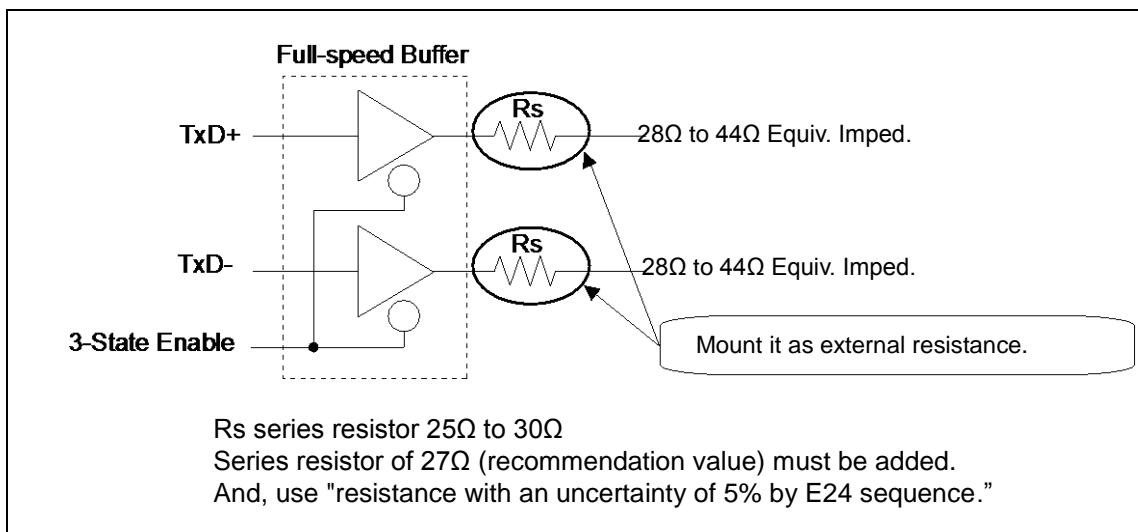

\*5: They indicate rise time ( $T_{rise}$ ) and fall time ( $T_{fall}$ ) of the full-speed differential data signal. They are defined by the time between 10% and 90% of the output signal voltage. For full-speed buffer,  $T_r/T_f$  ratio is regulated as within  $\pm 10\%$  to minimize RFI emission.

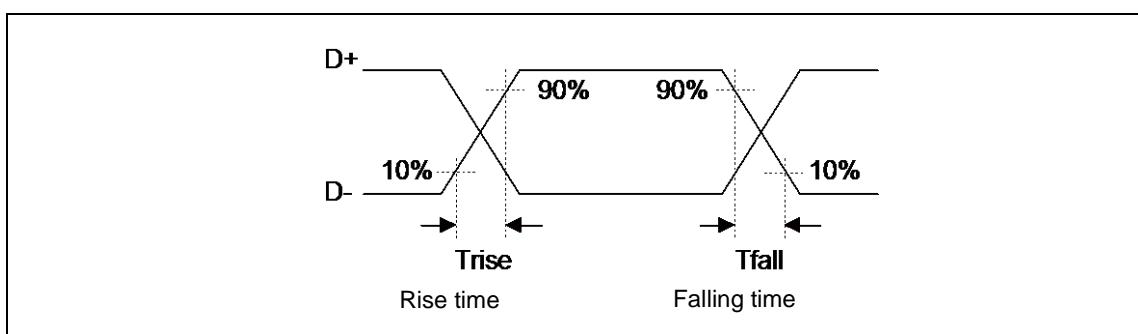

\*6: USB Full-speed connection is performed via twisted-pair cable shield with  $90\ \Omega \pm 15\%$  characteristic impedance (differential mode).

USB standard defines that the output impedance of the USB driver must be in the range from  $28\ \Omega$  to  $44\ \Omega$ . So, a discrete series resistor ( $R_s$ ) addition is defined in order to satisfy the above definition and keep balance. When using this USB I/O, use it with  $25\ \Omega$  to  $30\ \Omega$  (recommended value  $27\ \Omega$ ) series resistor  $R_s$ .

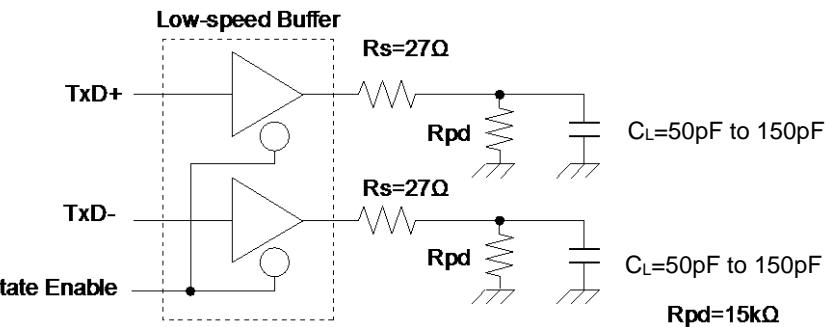

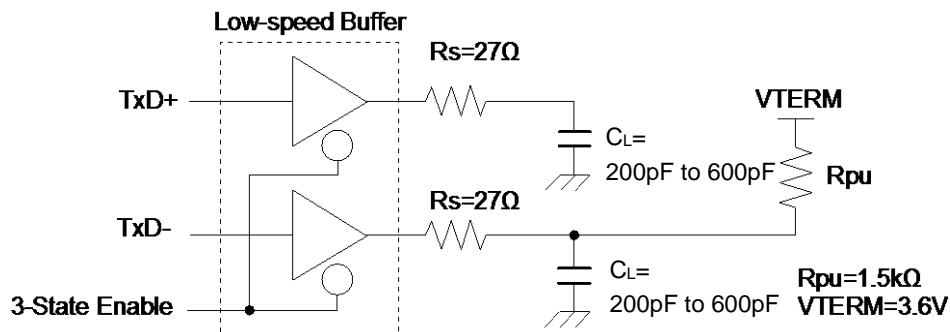

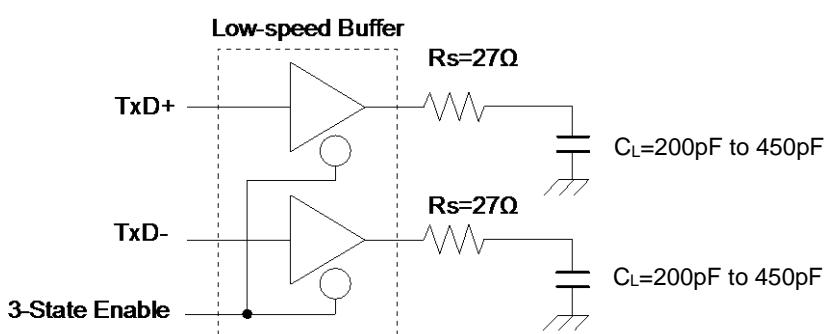

\*7: They indicate rise time ( $T_{rise}$ ) and fall time ( $T_{fall}$ ) of the low-speed differential data signal. They are defined by the time between 10% and 90% of the output signal voltage.
